**Abstract of the Disclosure**

*B5*

A device for administering a composition in a wall of a duct of a human or animal body includes a radially expandable member configured to enter a duct. Cutting elements project from an outer surface of the expandable member for making blind openings in the wall with the member in an expanded state. A composition-dispensing component includes a cuff which is slidable axially over the radially expandable member after the blind openings have been made and the radially expandable member has returned to a retracted state. Then, the member can be re-expanded to expand the cuff.
